Daniel Kersten

Introduction

Last time

Modeled aspects of spatial lateral inhibition in the visual system:

Simple linear network: intensity->spatial filter->response

intensity and response were represented as vectors

the spatial filter was represented as a matrix

If the spatial filter is a neural network, then the elements of the matrix can be interperted as strengths of synaptic connections. The idea is to represent the synaptic weights for the ith output neuron by the values in the ith row of the matrix. The matrix of weights is sometimes called a connection matrix just because non-zero weights are between connected neurons, and neurons that aren't connected get fixed zero weights.

This model is what we called a linear feedforward network, and used the generic neuron model.

We generalized the linear discrete model to a linear continous one with feedback. Although more complex, its steady-state solution is identical to the linear feedforward model.

We studied the continuous system by approximating it as a discrete time system with $\epsilon = \Delta t$ as a free parameter.

Today

There is a large body of mathematical results on linear algebra and matrices, and it is worth our while to spend some time going over some of the basics of matrix manipulation.

We will first review matrix arithmetic (addition and multiplication). We will review the analog of division, namely finding the inverse of a matrix--something that was used in Lecture 5 to show how the steady-state solution of the feedback model of lateral inhibition was equivalent to a feedforward model with the appropriate weights.

You may wonder at times how all this is used in neural modeling. But as this course goes on, we will see how otherwise obscure notions of things like an "outer product" between two vectors, or the "eigenvectors" of a matrix are meaningful for neural networks. For example, the "outer product" between two vectors can be used in modeling learning, and the eigenvectors corresponding to a "matrix of memories" can represent stored prototypes, and in dimensionality reduction.

Basic matrix arithmetic

A short motivation and preview

In Lecture 4, we developed the generic neural model. If we leave out the non-linear squashing function and noise, we have a linear neural nework.

$$y_i = \sum w_{i,j} x_j$$

In Lecture 5, we noted that the feedforward model of lateral inhibition does a good job of characterizing the neural response of visual receptors in the limulus. We implemented the feedforward linear model of lateral inhibition by taking the dot product of a weight vector with the input vector at one location, then we shifted the weight vector over, took a new dot product, and so forth.

But this operation can be expressed as a matrix, W, times a vector, e, using the linear model of a neural network:

$$y_i = \sum W_{i,j} e_j$$

W.e is short-hand for: $\sum W_{i,j} e_i$

To illustrate, define e as we did in the previous lecture, but over a shorter width (so the output display isn't too big):

Out[2]//MatrixForm=

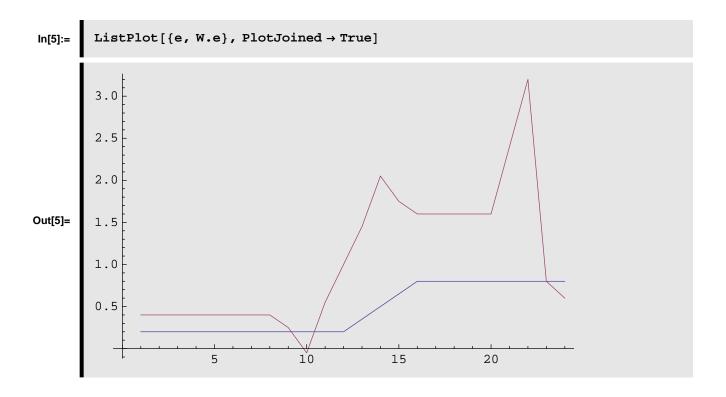

```

0.8
```

Take the same weights we used in the previous lecture and make a 24x24 matrix in which the first row is: -1,-1,6,1,1,0,0,...,

and the rows above are versions of the above row shifted one place to the right.

```
RotateLeft[
  0, 0, 0, 0, 0, 0, 0, 0}], 2]
Out[3]=
  \{0, 0, 0, 0, 0, 0, 0, 0, -1, -1, 6, -1, -1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0\}
  \{0, 0, 0, 0, 0, 0, 0, 0, 0, -1, -1, 6, -1, -1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0\}
  \{0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, -1, -1, 6, -1, -1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0\}
  \{0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, -1, -1, 6, -1, -1, 0, 0, 0, 0, 0, 0, 0, 0\}
  \{0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, -1, -1, 6, -1, -1, 0, 0, 0, 0, 0, 0\}
```

(Ignore the Toeoplitz[] function for now. We use it as a "one-liner" to fill up the matrix with the appropriate weights).

Definition of a matrix: a list of scalar lists

Traditional and Standard form output format defaults.

■ Defining arrays or lists of function outputs using indices

As we've already seen, Table[] can be used to generate a matrix, or list of lists. E.g.

$$In[8]:=$$
 H = Table[i^2+j^2, {i, 1, 3}, {j, 1, 3}] // TraditionalForm

Out[8]//TraditionalForm=

$$\begin{pmatrix} 2 & 5 & 10 \\ 5 & 8 & 13 \\ 10 & 13 & 18 \end{pmatrix}$$

If you want to see the output in standard Mathematica form, use //StandardForm or StandardForm[].

Out[7]//StandardForm=

...try "% // TraditionalForm" to see it again in traditional form.

```
\begin{pmatrix} 2 & 5 & 10 \\ 5 & 8 & 13 \\ 10 & 13 & 18 \end{pmatrix}
```

■ Defining arrays or lists of symbols

Although most of the time, we'll be working with numerical matrices, *Mathematica* also allows one to specify arrays or lists of variables.

An mxn matrix has m rows, and n columns. Here is a 3x4 matrix of symbolic elements w[i,j]:

You can produce the same array with: **Table[w[i,j],{i,1,3},{j,1,4}]]**. You can also have *Mathematica* display a subscripted list

Out[11]//MatrixForm=

```
\begin{pmatrix} w_{1,1} & w_{1,2} & w_{1,3} & w_{1,4} \\ w_{2,1} & w_{2,2} & w_{2,3} & w_{2,4} \\ w_{3,1} & w_{3,2} & w_{3,3} & w_{3,4} \end{pmatrix}
```

Mathematica lists can have elements of with a variety types:

In[16]:= L

Out[16]//MatrixForm=

```
\begin{pmatrix} 3 & w_{1,2} & w_{1,3} & w_{1,4} \\ w_{2,1} & w_{2,2} & 3. & \text{hi} \\ w_{3,1} & w_{3,2} & w_{3,3} & \pi \end{pmatrix}
```

Adding, subtracting and multiplying by a scalar

As with vectors, matrices are added, subtracted, and multiplied by a scalar component by component:

Add **A** to **B**:

In[21]:= A+B//TraditionalForm

Out[21]//TraditionalForm=

$$\begin{pmatrix} a+x & b+y \\ c+u & d+v \end{pmatrix}$$

Subtract **B** from **A**:

In[22]:= A-B//TraditionalForm

Out[22]//TraditionalForm=

$$\begin{pmatrix} a-x & b-y \\ c-u & d-v \end{pmatrix}$$

Multiply **A** by 3:

In[23]:= 3 A//TraditionalForm

Out[23]//TraditionalForm=

 $\begin{pmatrix} 3 a & 3 b \\ 3 c & 3 d \end{pmatrix}$

Multiplying two matrices

We have already seen how to multiply a vector by a matrix: we replace the ith row (i.e. element) of the output vector by the inner (dot) product of the ith row of the matrix with the input vector.

In order to multiply a matrix \mathbf{A} , by another matrix \mathbf{B} to get $\mathbf{C} = \mathbf{A}\mathbf{B}$, we calculate the ijth component of the output matrix by taking the inner product of the ith row of \mathbf{A} with the jth column of \mathbf{B} :

```
In[24]:= A.B//TraditionalForm
```

Out[24]//TraditionalForm=

```
\begin{pmatrix} b u + a x & b v + a y \\ d u + c x & d v + c y \end{pmatrix}
```

Note that **AB** is not necessarily equal to **BA**:

```
B.A//TraditionalForm
Out[25]//TraditionalForm=
```

```
\begin{pmatrix}
a x + c y & b x + d y \\
a u + c v & b u + d v
\end{pmatrix}
```

Laws of commutation, association and distribution

In particular, look at the element in the upper left of the matrix **BA** above--there is no reason, in general, for **ax+bu** to equal $\mathbf{ax} + \mathbf{cy}$. That is, matrix multiplication does not *commute*.

Apart from commutation for matrix multiplication, the usual laws of commutation, association, and distribution that hold for scalars hold for matrices. It is easy to see that matrix addition and subtraction do commute--e.g. compare A+B with **B+A.** Matrix multiplication is associative, so (AB)C = A(BC). The distributive law works too: A(B+C) = AB + AC

Non-square matrices

It is not necessary for A and B to be square matrices (i.e. have the same number of rows as columns) to multiply them. But if A is an mxn matrix, then B has to be an nxp matrix in order for AB to make sense. In other words, the left matrix (A) has to have the same number of columns as the right matrix (B) has rows.

For example, here \mathbf{F} is a 3x2 matrix, and \mathbf{G} is a 2x4 matrix.

```
Clear[e];
F = {{a,b},{c,d},{e,f}}
G = {{p,q,r,s},{t,u,v,w}}
In[26]:=
          {{a, b}, {c, d}, {e, f}}
Out[27]=
         {{p, q, r, s}, {t, u, v, w}}
Out[28]=
```

Check the dimensions with

```
In[29]:= Dimensions[F]
Dimensions[G]

Out[29]= {3, 2}

Out[30]= {2, 4}
```

Because **F** has 2 columns, and **G** has 2 rows, it makes sense to multiply **G** by **F**:

In[36]:= Print[F // TraditionalForm, G // TraditionalForm, " = ", F.G // TraditionalForm]
$$\begin{pmatrix} a & b \\ c & d \\ e & f \end{pmatrix} \begin{pmatrix} p & q & r & s \\ t & u & v & w \end{pmatrix} = \begin{pmatrix} ap+bt & aq+bu & ar+bv & as+bw \\ cp+dt & cq+du & cr+dv & cs+dw \\ ep+ft & eq+fu & er+fv & es+fw \end{pmatrix}$$

However, because the number of columns of G (4) do not match the number of rows of F (3), G.F is not well-defined:

Try this:

```
In[37]:= Print[F, G, " =", G.F]
```

Inverse of a Matrix

"Dividing" a matrix by a matrix: the identity matrix & matrix inverses

The matrix corresponding to 1 or unity is the **identity matrix**. Like 1, the identity matrix is fundamental enough, that *Mathematica* provides a special function to generate n-dimensional identity matrices. Here is a 2x2:

It is easy to show that the identity matrix plays the role for matrix arithmetic that the scalar 1 plays for scalar arithmetic:

Out[39]//MatrixForm=

which is just A.

What could it mean to divide one matrix, say \mathbf{B} , by another, say \mathbf{A} ? We can divide numbers, x by y, by multiplying x times the inverse of y, i.e. 1/y. So to do the equivalent of dividing \mathbf{B} by \mathbf{A} , we need to find a matrix \mathbf{Q} such that when \mathbf{A} is multiplied by \mathbf{Q} , we get the matrix equivalent of unity, i.e. the identity matrix. Then " \mathbf{B}/\mathbf{A} " can be achieved by calculating the matrix product: $\mathbf{B}.\mathbf{Q}$.

$$In[40]:=$$
 A = {{a,b},{c,d}};

Mathematica provides a built-in function to compute matrix inverses:

Out[47]:=
$$Q = Inverse[A]$$

$$\left\{ \left\{ \frac{d}{-bc+ad}, -\frac{b}{-bc+ad} \right\}, \left\{ -\frac{c}{-bc+ad}, \frac{a}{-bc+ad} \right\} \right\}$$

We can test to see whether the product of a A and Q is the identity matrix, but *Mathematica* won't go through the work of simplifying the algebra in this case, unless we specifically ask it to.

In[48]:= Q.A

Out[48]=
$$\left\{ \left\{ -\frac{bc}{-bc+ad} + \frac{ad}{-bc+ad}, 0 \right\}, \left\{ 0, -\frac{bc}{-bc+ad} + \frac{ad}{-bc+ad} \right\} \right\}$$

Out[50]//TraditionalForm=

$$\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

Here is a simple numerical example. Verify that R is the inverse of B by seeing whether the product is the Identity matrix.

In[51]:= B = {{1,-1},{3,2}};
R = Inverse[B]

Out[52]=
$$\left\{ \left\{ \frac{2}{5}, \frac{1}{5} \right\}, \left\{ -\frac{3}{5}, \frac{1}{5} \right\} \right\}$$

Singular and badly conditioned matrices

You might have noticed that elements of the inverse matrix could have zero denominators if we happened to have unfortunate values of a,b,c,d. In general, the inverse of a matrix is not guaranteed to exist. Let's look at the conditions for which the inverse is not defined.

What if one row is a scaled version of another row?

Then the rows of the matrix are not linearly independent. In other words, one row can be expressed as a scaled version of the other row. In general, a set of row vectors is linearly independent if for any row you can't write it as a linear combination of any of the others. In this case, the inverse is not defined and is said to be *singular*.

Ask for the inverse of B1

Inverse::sing: Matrix $\{\{1.5, 1.\}, \{3., 2.\}\}\$ is singular. \gg

Out[55]//TraditionalForm=

$$\left(\begin{array}{cc} 1.5 & 1 \\ 3 & 2. \end{array}\right)^{-1}$$

Sometimes the rows are almost, but not quite, linearly dependent (because the elements are represented as approximate floating point approximations to the actual values). *Mathematica* may warn you that the matrix is badly conditioned. Mathematica may try to find a solution to the inverse, but you should be suspicious of the solution. In general, one has to be careful of badly conditioned matrices.

Try finding the inverse of the following matrix:

```
In[56]:= B2 = {{-2,-1},{4.000000000001,2.0}};
Inverse[B2]
```

Inverse::luc:

Result for Inverse of badly conditioned matrix $\{\{-2., -1.\}, \{4., 2.\}\}$ may contain significant numerical errors. \gg

```
Out[57]= \left\{ \left\{ 2.04709 \times 10^{14} , \ 1.02355 \times 10^{14} \right\}, \ \left\{ -4.09418 \times 10^{14}, \ -2.04709 \times 10^{14} \right\} \right\}
```

Were we lucky or not?

```
In[58]:= B2.Inverse[B2]
```

Inverse::luc:

Result for Inverse of badly conditioned matrix $\{\{-2, -1, \}, \{4, 2, \}\}$ may contain significant numerical errors. \gg

Out[58]= { {1., 0.}, {0., 1.}}

Determinant of a matrix

There is a scalar function of a matrix called the determinant. If a matrix has an inverse, then its determinant is non-zero. Does **B2** have an inverse?

```
In[59]:= Det[B2]
Out[59]= 9.76996×10<sup>-15</sup>
```

Yes, but it is suspiciously small. But **B** has a solid non-zero determinant.

```
In[60]:= Det[B]
Out[60]= 5
```

Matrix transpose

Transpose definition

We will use the transpose operation quite a bit in this course. It interchanges the rows and columns of a matrix:

```
In[97]:= Y = Table[y<sub>i,j</sub>, {i, 1, 3}, {j, 1, 4}];
% // TraditionalForm
```

Out[98]//TraditionalForm=

```
\begin{pmatrix} y_{1,1} & y_{1,2} & y_{1,3} & y_{1,4} \\ y_{2,1} & y_{2,2} & y_{2,3} & y_{2,4} \\ y_{3,1} & y_{3,2} & y_{3,3} & y_{3,4} \end{pmatrix}
```

```
In[70]:= Transpose[Y] // TraditionalForm
```

Out[70]//TraditionalForm=

```
\begin{pmatrix} y_{1,1} & y_{2,1} & y_{3,1} \\ y_{1,2} & y_{2,2} & y_{3,2} \\ y_{1,3} & y_{2,3} & y_{3,3} \\ y_{1,4} & y_{2,4} & y_{3,4} \end{pmatrix}
```

The output default is TraditionalForm. On the input line, in TraditionalForm, the transpose is written:

```
In[99]:= Y^T // TraditionalForm
StandardForm[%]
```

Out[99]//TraditionalForm=

```
\begin{pmatrix} y_{1,1} & y_{2,1} & y_{3,1} \\ y_{1,2} & y_{2,2} & y_{3,2} \\ y_{1,3} & y_{2,3} & y_{3,3} \\ y_{1,4} & y_{2,4} & y_{3,4} \end{pmatrix}
```

Out[100]//StandardForm=

$$\left\{ \left\{ y_{1,1},\; y_{2,1},\; y_{3,1} \right\},\; \left\{ y_{1,2},\; y_{2,2},\; y_{3,2} \right\},\; \left\{ y_{1,3},\; y_{2,3},\; y_{3,3} \right\},\; \left\{ y_{1,4},\; y_{2,4},\; y_{3,4} \right\} \right\}$$

Getting parts of a matrix

(See the *Mathematica* documentation: tutorial/GettingAndSettingPiecesOfMatrices)

We've seen before how to get the ijth element, in other words the element in the ith row and jth column. We type W[[i,j]] or W[[i]][[j]].

We can pull out the i^{th} row of a matrix in *Mathematica* by simply writing W[[i]]. For example, the 2nd row of Y is:

```
In[75]:= Y[[2]]
Out[75]= \{Y_{2,1}, Y_{2,2}, Y_{2,3}, Y_{2,4}\}
```

What about the jth column of a matrix? **W[[All,j]]** produces the jth column of matrix **W**. To get the 3rd column of a matrix in *Mathematica*, type:

```
In[78]:= Y[[All, 3]]
Out[78]= \{Y_{1,3}, Y_{2,3}, Y_{3,3}\}
```

We can also use the transpose operation to do it. Transpose[W][[i]] produces the jth column of matrix W. For example, the 3nd column of Y is:

```
In[79]:= Transpose[Y][[3]]

Out[79]= \{Y_{1,3}, Y_{2,3}, Y_{3,3}\}
```

Try putting //ColumnForm after the above expression.

To pull out a submatrix with rows i0 through i1, and columns j0 through ji, type: $\mathbf{W}[[i_0 \; ;; \; i_1, \; j_0 \; ;; \; j_1]]$

```
In[82]:= Y[[2;;3,1;;3]] // TraditionalForm
```

Out[82]//TraditionalForm=

```
\begin{pmatrix} y_{2,1} & y_{2,2} & y_{2,3} \\ y_{3,1} & y_{3,2} & y_{3,3} \end{pmatrix}
```

And here is yet another way:

```
Y[[Range[2, 3], Range[1, 3]]]
\begin{pmatrix} y_{2,1} & y_{2,2} & y_{2,3} \\ y_{3,1} & y_{3,2} & y_{3,3} \end{pmatrix}
```

Pull out the element y_{2,3}from Y

Symmetric matrices

For a square matrix, the diagonal elements remain the same under transpose.

If the transpose of a matrix equals itself, $\mathbf{H}^T = \mathbf{H}$, \mathbf{H} is said to be a **symmetric matrix.** Symmetric matrices occur quite often in physical systems (e.g. the force on particle i by particle j is equal to the force of j on i). This means that the elements of a symmetric matrix \mathbf{H} look like they are reflected about the diagonal. We constructed a symmetric matrix in Lecture 5 when we modeled the exponential drop-off in lateral inhibition:

```
In[101]:= H = Table[N[Exp[-Abs[i-j]],1],{i,5},{j,5}];
%//TraditionalForm
```

Out[102]//TraditionalForm=

```
 \begin{pmatrix} 1. & 0.4 & 0.1 & 0.05 & 0.02 \\ 0.4 & 1. & 0.4 & 0.1 & 0.05 \\ 0.1 & 0.4 & 1. & 0.4 & 0.1 \\ 0.05 & 0.1 & 0.4 & 1. & 0.4 \\ 0.02 & 0.05 & 0.1 & 0.4 & 1. \end{pmatrix}
```

(The notion of a Hermitian matrix is a generalization of symmetric, where $H^* = H$, and H^* is the transpose of the complex conjugate of H.)

Neural networks and symmetric connections

Do neural systems have symmetric connections? Most real neural networks probably do not. Although, when the nature of the processing would not be expected to favor a particular asymmetry, we might expect that there should be symmetric connections on average. We made this assumption when setting up our lateral inhibition weight matrix, as seen above for **H**. Symmetric matrices have so many nice properties, that they are appealing to neural modelers on theoretical grounds. We'll see this later when we study the Hopfield networks. Lack of symmetry can have profound effects on the dynamics of non-linear networks and can produce "chaotic" trajectories of the state vector.

Outer product of two vectors

We've already seen that the inner product of two vectors produces a scalar. In the next lecture, we will begin our discussion of Hebbian learning in neural networks. In this context, the **outer product** of an input and output vector will be used to model synaptic modification. Consider two vectors:

The outer product is just all of the pairwise products of the elements of f and g arranged in a nice (and special) order:

```
In[105]:= h = Outer[Times,fv,gv];
%//TraditionalForm
```

Out[106]//TraditionalForm=

```
\begin{pmatrix} f_1 \, g_1 & f_1 \, g_2 & f_1 \, g_3 \\ f_2 \, g_1 & f_2 \, g_2 & f_2 \, g_3 \\ f_3 \, g_1 & f_3 \, g_2 & f_3 \, g_3 \end{pmatrix}
```

To get a preview of things to come, we'll see how to model some aspects of learning usin the idea of a "Hebbian synase". The idea in Hebbian learning is that an adjustment to the strength of a connection between say the ith and jth neurons is proportional to the product of the strength of pre- and post-synaptic activities, represented by g_i and f_i .

The outer product is also written in traditional row and column format as: $\mathbf{f} \, \mathbf{g}^T$

$$\mathbf{f}\mathbf{g}^{\mathbf{T}} = \begin{pmatrix} \mathbf{f}_1 \\ \mathbf{f}_2 \\ \mathbf{f}_3 \end{pmatrix} (\mathbf{g}_1 \ \mathbf{g}_2 \ \mathbf{g}_3) \tag{1}$$

We'll also use outer product to calculate autocorrelation matrices.

Eigenvectors and eigenvalues

Basic idea

Eigenvalues and eigenvectors crop up in many ways. For example, the solution to a set of linear first-order (i.e. no derivative orders bigger than 1) differential equations can be found in terms of eigenvalues and eigenvectors. For a simplified version of the limulus equations

$$\frac{\mathrm{d}\mathbf{f}}{\mathrm{d}t} = \mathbf{A} \cdot \mathbf{f} \tag{2}$$

the solution is determined by the eigenvalues and eigenvectors of A and the initial conditions.

Eigenvectors also crop up in statistics and related neural network algorithms. For example, principal components analysis (PCA) is used in dimensionality reduction in statistics--also important in neural networks and "natural computation".

So what are eigenvalues, eigenvectors? An eigenvector, \mathbf{x} , of a matrix, \mathbf{A} , is vector that when you multiply it by \mathbf{A} , you get an output vector that points in the same (or opposite, depending on the sign of λ) direction as \mathbf{x} :

$$\mathbf{A}\mathbf{x} = \lambda \mathbf{x}$$

where λ is an eigenvalue--a scalar that adjusts the length change of **x**. The eigenvalues are found by solving:

Det[A- λ Id]==0, for λ where Id is the identity matrix.

Mathematica provides a one-step function to return the eigenvalues and eigenvectors of a matrix. But let's review how one might go about finding the eigenvalues of a matrix A in smaller steps:

In[107]:=
$$A = \{\{1,2\},\{3,4\}\};$$

In[108]:= $Id = IdentityMatrix[2]$

Out[108]= $\{\{1,0\},\{0,1\}\}$

In[109]:= $Solve[Det[A - \lambda * Id] == 0, \lambda]$

Out[109]= $\{\{\lambda \to \frac{1}{2} (5 - \sqrt{33})\}, \{\lambda \to \frac{1}{2} (5 + \sqrt{33})\}\}$

Now pick one of the solutions for λ , find the vector $\mathbf{x} = \{x_1, x_2\}$ that satisfies the basic definition, $\mathbf{A}.\mathbf{x} = \lambda \mathbf{x}$

In[110]:= Solve
$$\left[\left\{A.\left\{x_{1}, x_{2}\right\} = \frac{1}{2}\left(5-\sqrt{33}\right) * \left\{\left\{1, 0\right\}, \left\{0, 1\right\}\right\}.\left\{x_{1}, x_{2}\right\}\right\}, \left\{x_{1}\right\}\right] / /$$
Simplify

Out[110]:= $\left\{\left\{x_{1} \to -\frac{1}{6}\left(3+\sqrt{33}\right) x_{2}\right\}\right\}$

So any multiple of

$$\mathbf{x} = \left\{1, -\frac{1}{6} \left(\sqrt{33} + 3\right)\right\}$$

$$\left\{1, \frac{1}{6} \left(-3 - \sqrt{33}\right)\right\}$$

is a valid eigenvector.

From algebra, because the **Det**[]==0 is a polynomial of order n, there can't be any more than n distinct solutions, i.e. eigenvectors for an nxn matrix--and there may be less.

We can similarly find the second distinct eigenvector for $\lambda \to \frac{1}{2} \left(5 + \sqrt{33}\right)$, but *Mathematica* provides a simpler way of doing things.

Built-in functions for finding eigenvalues and eigenvectors

■ Eigenvalues[]

The eigenvalues are given by:

In[111]:= Eigenvalues[A]

Out[111]=
$$\left\{\frac{1}{2}\left(5+\sqrt{33}\right), \frac{1}{2}\left(5-\sqrt{33}\right)\right\}$$

Eigenvalues and eigenvector elements do not have to be real numbers. They can be complex, that is an element can be the sum of a real and imaginary number. Imaginary numbers are represented by multiples (or fractions) of **I**, the square root of -1:

Out[113]//OutputForm=

In[114]:=
$$B = \{\{1,2\}, \{-3,4\}\};$$

Eigenvalues[B]

In[114]:=
$$B = \{\{1,2\}, \{-3,4\}\};$$
Eigenvalues[B]
$$\left\{ \frac{1}{2} \left(5 + i \sqrt{15} \right), \frac{1}{2} \left(5 - i \sqrt{15} \right) \right\}$$

■ Eigenvectors[]

The built-in *Mathematica* function **Eigenvectors**[A] returns the eigenvectors of matrix A as the rows of a matrix, lets call eig:

In[116]:= eig = Eigenvectors[A]

Out[116]:=
$$\left\{ \left\{ -\frac{4}{3} + \frac{1}{6} \left(5 + \sqrt{33} \right), 1 \right\}, \left\{ -\frac{4}{3} + \frac{1}{6} \left(5 - \sqrt{33} \right), 1 \right\} \right\}$$

Verify that eig[[1]] and A.eig[[1]] lie along the line (i.e. in the same or opposite directions) by taking the dot product of the unit vectors pointing in the directions of each. Use the Normalize[] function:

Linear systems analysis & introduction to learning/memory

In the next lecture, we'll apply what we've learned about matrices and vectors to two problems. We'll first take an in-depth look at the properties of the linear neural network to see how it relates to general linear systems. We'll also show the advantages of using the eigenvectors of the linear transformation matrix as a useful coordinate system to represent input and output pattern vectors.

We will introduce the topic of learning and memory, and see how the outer product rule can be used to model associative learning.

Preview of linear systems analysis

Linear systems are an important, and tractable class of input/output models. Matrix operations on vectors provide the prototype linear system.

Consider the generic 2-layer network, i.e. with 1 input set of units, and 2 output set. Each output neuron takes a weighted average of the inputs (stage 1), followed by a point-nonlinearity (the squash function of stage 2), and added noise (stage 3). Although later we will see how the non-linearity enables computations that are not possible without it, useful functions can be realized with just the linear or stage 1 part of the network. We've seen one application already with the model of the limulus eye. In the next lecture, we will see how linear networks can be used to model associative memory. But first, let us take what we've learned so far about modeling linear networks and look at in the general context of linear systems theory. Our 2-layer net is a matrix of weights that operates on a vector of input activities ty computing a weighted sum. One property of such a system is that it satisfies the fundamental definition of a "linear system", which we will define shortly.

The world of input/output systems can be divided up into linear and non-linear systems. Linear systems are nice because the mathematics that describes them is not only well-known, but also has a mature elegance. On the other hand, it is a fair statement to say that most real-world systems are not linear, and thus hard to analyze...but fascinating if for that reason alone. Scientists were lucky with the limulus eye. That nature is usually non-linear doesn't mean one shouldn't familiarize oneself with the basics of linear system theory. Many times non-linear systems can be approximated by a linear one over some restricted range of parameter values.

So what is a "linear system"?

The notion of a "linear system" is a generalization of the input/output properties of a straight line passing through zero. The matrix equation $\mathbf{W}.\mathbf{x} == \mathbf{y}$ is a linear system. This means that if \mathbf{W} is a matrix, $\mathbf{x}\mathbf{1}$ and $\mathbf{x}\mathbf{2}$ are vectors, and a and b are scalars:

$$W.(a x1 + b x2) = a W.x1 + b W.x2$$

This is a consequence of the laws of matrix algebra. The idea of a linear system has been generalized beyond matrix algebra. Imagine we have a box that takes inputs such as f, and outputs g = T[f].

The abstract definition of a linear system is that it satsifies:

$$T[a f + b g] = a T[f] + b T[g]$$

where T is the transformation that takes the sum of scaled inputs f, g (which can be functions or vectors) to the sum of the scaled transformation of f and g. The property, that the output of a sum is the sum of the outputs, is sometimes known as the *superposition principle* for linear systems. The fact that linear systems show superposition is good for doing theory, and modeling some kinds of neural processing, but as we will see later, superposition limits the kind of computations that can be done with linear systems, and thus with linear neural network models.
